Abstract

Local firms may attract productivity spillovers from foreign investors, yet these vary with local firms' awareness, capability and motivation to react to foreign entry. In consequence, spillovers vary across countries at different levels of economic development. We apply competitive dynamics theory to analyze these contextual moderators of spillovers, and test hypotheses thus derived in a meta-analysis of the empirical literature on spillovers. Our analysis suggests a curvilinear relationship between spillovers and the host country's level of development in terms of income, institutional framework and human capital. *Journal of International Business Studies* (2009) 40, 1075–1094.

INTRODUCTION

Local firms experience inward foreign direct investment (FDI) as both a competitor and a source of advanced technologies and managerial knowledge. However, the scale and scope of such spillovers vary with firms' characteristics (Feinberg & Majumdar, 2001; Sinani & Meyer, 2004) and the context in which they are interacting (Blomstrom & Kokko, 2003; Keller, 1996).

Development economists emphasize that spillover benefits may increase with the technology gap between local recipient firms and the foreign investors (Findlay, 1978; Perez, 1997; Wang & Blomstrom, 1992). However, this effect may be important only for developing countries. Management scholars emphasize that firms' response to entry in their industry is crucially dependent on their own awareness, motivation and capability (Chen, 1996; Smith, Ferrier, & Ndofor, 2001). Firms' own capability is crucial to make use of knowledge that they can access (Blomstrom & Kokko, 2003; Keller, 1996; Rogers, 2004), while direct competition without institutional protection creates stronger motivation to react (Baum & Korn, 1996). We thus extend Chen's (1996) awareness-motivation-capability framework to explain cross-contextual variations of local firms' productivity upgrading in response to foreign entry.

These dynamics of competition lead to a nonlinear relationship between economic development and received spillovers. In low-income economies, a large technological gap may permit

conventional demonstration effects. With economic development, these benefits decline, while foreign investors become more likely to compete directly with local firms and thus to cause crowding-out effects (Aitken & Harrison, 1999). However, at advanced levels of economic development, local firms also develop their motivation and capability to react to foreign entry. Beyond a certain threshold, they are likely to generate net benefits from the interaction with inward investors based on their own capability to absorb latest technologies, and to react to increased competition by upgrading their productivity.

Economic development encompasses many closely related dimensions. At an aggregate level, it is associated with higher levels of per capita income (Borensztein, Gregorio, & Lee, 1998). Underlying economic development, however, are the institutional development and the endowment of the country with resources, especially human capital (De Mello, 1997; Hirschman, 1958; World Bank, 1993). We thus hypothesize a curvilinear relationship between spillovers from FDI and multiple dimensions of development, namely per capita income, human capital and institutional frameworks. This is confirmed in our empirical analysis.

Our methodology, a meta-analysis, takes advantage of the extensive empirical literature on FDI spillovers. Meta-analysis can play a crucial role in advancing scientific knowledge from context-specific knowledge to general theory. Many studies create context-specific knowledge because their data do not allow clear identification of boundary conditions (Meyer, 2006, 2007; Tsui, 2004). However, business scholarship aims to create general knowledge in the form of universally valid theorems (Huff, 1999; Tung & van Witteloostuijn, 2008), which requires cross-contextual analysis to validate the generalizability of results (Cheng, 1994; Rosenzweig, 1994). A meta-analysis provides a powerful tool to identify the moderating effects of contextual variables, and thus to establish the boundary conditions of scientific knowledge.

We build on an earlier meta-analysis by Gorg and Strobl (2001). Many studies test for spillovers by estimating a production function with FDI in the industry as an explanatory variable: a significant positive impact of this proxy on firms' productivity provides support for positive spillovers. Yet we lack understanding of whether and how these results are affected by the specific context, because most of these studies are single-country studies.¹ We thus conduct a meta-analysis to investigate an issue for

theory development, rather than to assert the average effect or methodological issues affecting the results. Contextual variation is analyzed through country-level variables rather than controlled for by dummies. Moreover, we improve over Gorg and Strobl (2001) by including three times as many research papers, employing random effects meta-analysis, and controlling for additional study characteristics.

Our results show that productivity spillovers are related in a U-shaped form to the host country's level of development in terms of per capita income, human capital and institutional development, while trade openness has a positive effect. These results have implications not only for theory development and the design of future empirical studies, but also for economic policy. Countries that develop from low levels progressively face stronger direct competition between local and foreign investment firms, while demonstration effects decline. However, beyond a threshold, development strengthens local firms' motivation and capability to counter competitive challenges of FDI, and thus to attract knowledge spillovers.

ECONOMIC DEVELOPMENT AND SPILLOVERS

The competitive interaction between local and foreign firms evolves with economic development. Where they are separated by large gaps in technology, locals have a lot to learn, and can thus potentially attract major knowledge spillovers (Findlay, 1978; Wang & Blomstrom, 1992). This "technology gap" indicates potential for catching up, and thus explains part of the cross-national variations in received spillovers (Lorentzen, 2005).

However, learning depends crucially on actions by the recipient firms themselves. In particular, competitive dynamics theory suggests that firms need appropriate *awareness, motivation, and capabilities* to react to entrants competing for their markets and resources (Chen, Su, & Tsai, 2007; Smith, Grimm, Gannon, & Chen, 1991). These factors also vary across countries, and contribute to the international variation of realized spillovers.

Technology Gap

Local firms learn from foreign investors, for instance by observing technologies employed by multinational enterprises (MNEs) (Kokko, 1992; Wang & Blomstrom, 1992), or by attracting employees that have been trained by MNEs (Meyer, 2004; Spencer, 2008). These demonstration effects depend on the local firms' catch-up potential:

relatively backward firms may increase their productivity even by imperfect copying of advanced practices, whereas firms operating close to the foreign investors' level of technology would gain little from copying easily observable aspects of their business.

Hence the *potential* for productivity improvements is positively related to the technology gap between local and foreign firms in an industry. A stream of theoretical models demonstrates that, for a given level of foreign presence, spillovers increase with the technology gap between foreign and domestic firms (Findlay, 1978; Perez, 1997; Wang & Blomstrom, 1992).

However, despite considerable empirical research, evidence for this "technology gap hypothesis" is weak (Haddad & Harrison, 1993; Kokko, 1994; Kokko, Tasini, & Zejan, 1996; Sjöholm, 1999). This lack of support may be because the assumptions underlying the hypothesis are reasonable only under specific conditions. In particular, it is assumed that the technology can be easily observed, for instance by reverse engineering. Moreover, the knowledge needs to be *non-proprietary* in the sense that the foreign investor is not preventing its diffusion. These conditions may apply to standardized technologies and practices that do not form part of the foreign investors' core competences. Local firms in developing countries may still find such basic knowledge beneficial to improve their productivity (Lall, 1978). In other contexts, it is much less likely to be relevant. Once foreign investors recognize local firms as potential competitors, rather than as needy recipients of development aid, they can be expected to increase measures to prevent knowledge diffusion.

Awareness

Foreign investment represents a high-profile form of entry, compared with international trade, and local firms are thus normally aware of these entrants. Yet they may not always comprehend the potential impact on their own business - either in terms of competition, or in terms of the learning potential. Such awareness of entrants' potential impact on their own business depends on the similarity of their operations and markets (Chen, 1996; Yu & Cannella, 2007).

Yet foreign investors' operations are often distinctly different from those of local firms because they compete on the basis of firm-specific resources (or "ownership advantages"; Dunning, 1988) transferred from other units of the MNE (Rugman,

1981). These firm-specific resources that allow the liability of foreignness to be overcome are typically based on intangible assets, such as brands and technology. Moreover, foreign investors have frequently been noted to employ more capital-intensive methods of production than have local firms in developing countries. In consequence, they typically operate in more up-market segments, where they experience little direct interaction with local firms operating in volume-driven mass markets with small margins (Dawar & Chattopadhyay, 2002). Moreover, foreign investors that manufacture for export have limited competitive interaction with firms operating locally, even when classified in the same sector of industry.

This limited interaction and low similarity reduces managers' cognizance of the relationship with the entrant, and thus reduces their awareness of the potential impact on their own business (Chen et al., 2007). Thus, in countries where operations of foreign and local firms are quite dissimilar, awareness of the likely impact of the foreign investment is likely to be low.

Motivation

Foreign investment intensifies competition in the industry it enters, both by increasing the number of competitors, and by introducing new ways to compete (Blomstrom & Kokko, 2003; Driffield & Love, 2007; Dunning, 1988). Local firms may adapt their strategies to counter the challenge, and thus to raise their competitive edge (Bowen & Wiersema, 2005). However, their reaction depends on their motivation and thus on the incentives they face (Chen et al., 2007; Smith et al., 1991).

These incentives are shaped by the institutional framework, especially the effectiveness of both domestic and international markets (North, 1990; Peng, Wang, & Jiang, 2008) and the national innovation system (Lundvall, Johnson, Andersen, & Dalum, 2002; Nelson, 1993). Institutional frameworks establish incentives and business practices that influence the nature of competition and knowledge acquisition processes. A pivotal aspect is the liberalization of international trade, which enhances both opportunities and incentives to innovate (Hoekman, Maskus, & Saggi, 2005; Keller, 1996).

Where local firms are subject to rules that constrain their options for restructuring, or protect them from the impact of competition, they have less motivation to engage in the often risky strategies of technological change and upgrading. Local firms may be most motivated to react to

foreign investors if the institutional framework provides them with the freedom to act, and generates incentives systems that reward innovation and strategic change.

Capability

Recipients have to connect new knowledge with existing knowledge, and to transform it for application in their own context. Firms' ability to do so varies as a result of their endowment with resources, especially human capital (Chen, 1996; Chen et al., 2007; Smith et al., 1991). This ability, also known as "absorptive capacity" (Cohen & Levinthal, 1990; Zahra & George, 2002), has been analyzed for specific business units (Lyles & Salk, 1996; Minbaeva, Pedersen, Bjorkman, Fey, & Park, 2003) and firms (Keller, 1996; Lai, Peng, & Bao, 2006; Rogers, 2004), as well as national economies (Borensztein et al., 1998; Criscuolo & Narula, 2008; Xu, 2000).

Absorptive capacity captures firms' ability to utilize acquired knowledge, and thus to increase their realized spillovers. Local firms that lack this capability may be unable to catch up, and may thus be crowded out by foreign investors. Similarly, local firms that only recently started facing foreign competitors, as in transition economies, may lack managerial resources to respond adequately or to raise their productivity (Konings, 2001). This can, at least in the short run, cause excess production capacity and thus low productivity (Aitken & Harrison, 1999).

The capability of potential recipient firms is a function of their human capital and their organizational structures that may facilitate innovation and thus enhance the benefits from received knowledge (Blomstrom & Kokko, 2003; Keller, 1996; Spencer, 2008). Moreover, this capability is closely associated with the level of income in the economy, which provides firms with the financial resources to acquire complementary resources, and to pay wages that match foreign investors' wages, and thus to benefit from attracting and retaining skilled employees (Aitken, Harrison, & Lipsey, 1996; Gershenberg, 1987).

HYPOTHESIS DEVELOPMENT

Many of the effects underlying spillovers have been shown to be nonlinear, including the relationship between learning and benefits from learning (Bjorkman, Stahl, & Vaara, 2007; Kotabe, Dunlap-Hinkler, Parente, & Mishra, 2007), the relationship between the intensity of competition and firms' strategic action (Chan, Makino, & Isobe, 2006), and

the technology gap and productivity spillovers (Buckley, Clegg, & Wang, 2007; Liu, Siler, Wang, & Wei, 2000). This suggests that the relationship we are investigating may be curvilinear as well.

Spillovers are conditioned by the local environment. We thus explore how characteristics of the host economy, and in particular its level of development, moderate the effects discussed above, with the aim of developing hypotheses regarding the strength of spillover effects across countries. To develop the argument, we first consider three scenarios of low-, middle- and high-income economies (Figure 1) before discussing the dynamics of changes in income levels (Figure 2).

Scenarios

Low-income economies. At low levels of development, the assumptions underlying the technology gap hypothesis may be appropriate. In such contexts, local firms may benefit from standardized knowledge that foreign investors do not prevent from diffusing, and which can be obtained by observation or indirect interactions. This would suggest that the technology gap argument is more relevant in developing economies (Findlay, 1978; Kokko, 1992), where some studies find empirical support (Jordaan, 2005; Wang & Yu, 2007).

Moreover, foreign investors in less developed economies are likely to operate in different market segments than local firms, and thus are not likely to compete directly (Dawar & Chattopadhyay, 2002; Spencer, 2008). While local firms often serve mass markets, foreign investors focus largely on premium segments and neglect the potential markets "at the bottom of the pyramid" (London & Hart, 2004; Prahalad, 2004). In addition, many foreign investors seek low-cost labor and natural resources, with the aim of serving export markets where they compete only indirectly with local firms (Spencer, 2008). This lack of direct competition reduces the local managers' awareness of the relevance of the foreign investors' experience for their own business (Chen, 1996). Moreover, segmentation and protection of markets may reduce motivation to react, while weak absorptive capacity reduces the capability to do so (Karpaty & Lundberg, 2004; Keller & Yeaple, 2003). Hence, in low-income economies, local firms are likely to benefit from demonstration effects due to a large technology gap, even though their *awareness*, *motivation* and *capability* for strategic reaction to foreign entry are low.

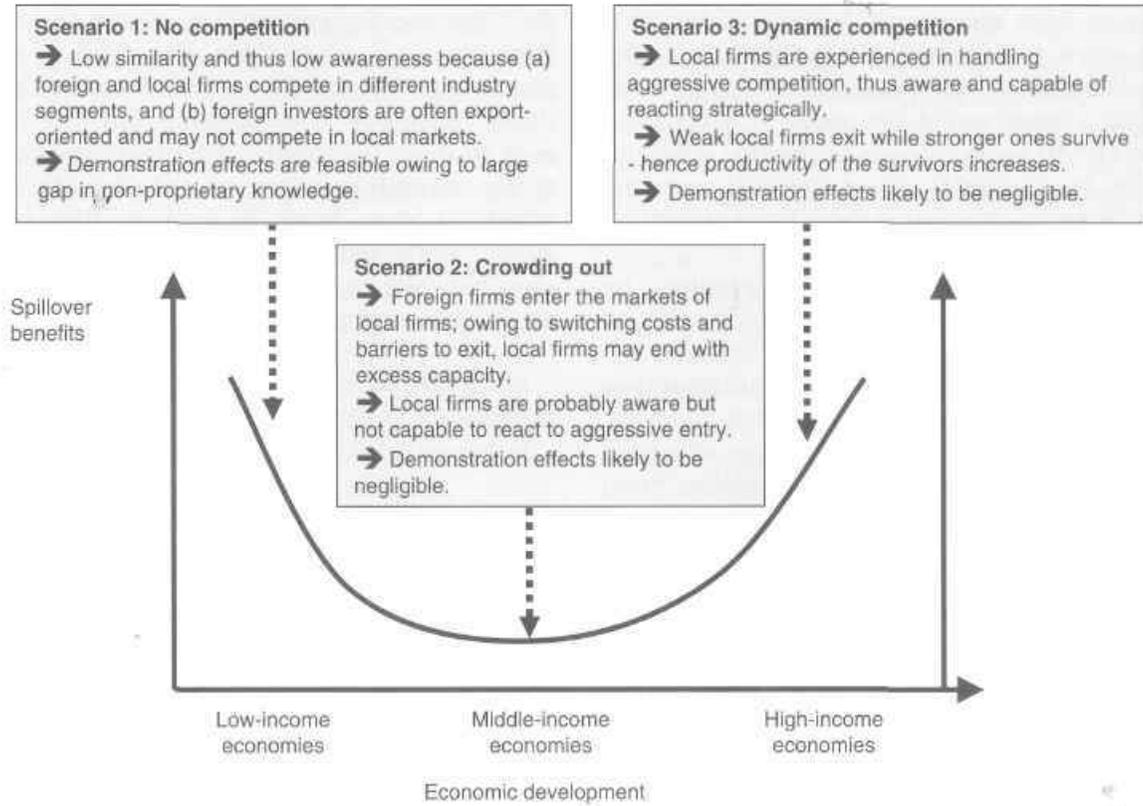

Figure 1 Likely spillovers from foreign investment in an industry.

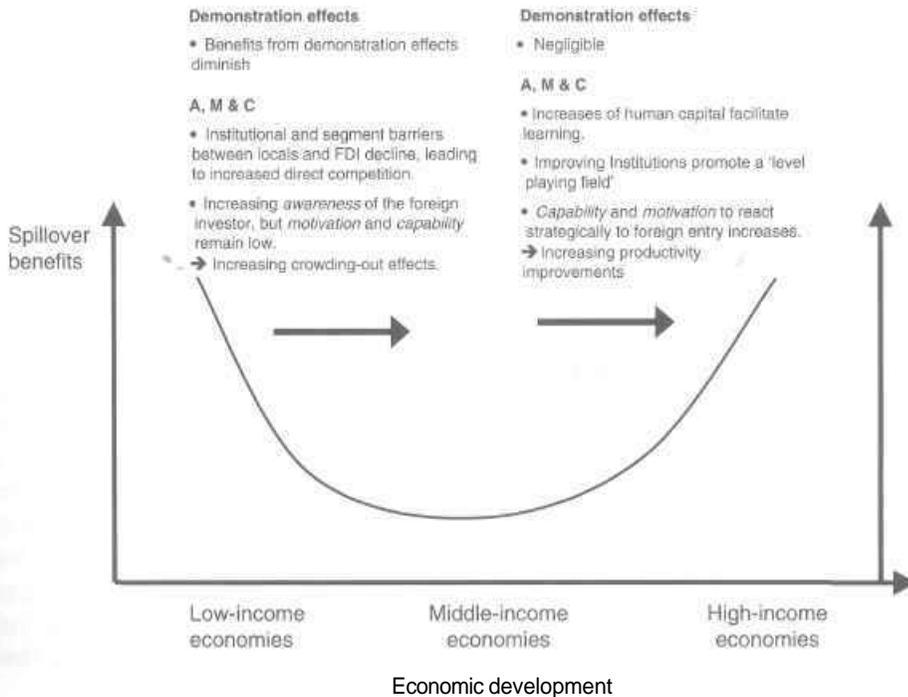

Figure 2 Evolution of spillover effects over economic development.

Medium-income economies. Local firms are more likely to compete with foreign investors when their products and technologies are more similar (Wang

& Blomstrom, 1992). In middle-income economies, foreign investors typically enter the same product and factor markets as local firms. Yet their

competitive edge may make it difficult for local firms to retain their market share (Spencer, 2008). This market-stealing effect causes excess capacity in local firms, as observed in Venezuela by Aitken and Harrison (1999) and in Spain by Barrios, Dimelis, Louri, and Strobl (2004). These types of economy are thus likely to experience local firms struggling in the face of FDI competition.

General knowledge that can be acquired by demonstration effects is unlikely to create substantive benefits in middle-income economies, where local firms normally would need advanced industry-specific capabilities to advance further. To the extent that foreign investors have more advanced technologies, these are usually proprietary, and cannot be easily observed and copied by indigenous firms (Javorcik, 2004). Hence demonstration effects are unlikely to be substantial. Thus awareness of foreign investors' impact is likely to be high in middle-income economies, yet, with weak capability, local firms are unlikely to be able to act strategically to attract benefits for themselves.

High-income economies. In advanced economies, inward investors normally compete directly with incumbent local firms in the same or similar market segments, such that awareness of the entrant is high. Moreover - in contrast to a typical middle-income economy - local firms usually have developed strong *capability* to compete successfully with the foreign entrants (Haskel, Pereira, Slaughter, & Matthew, 2007; Liu et al., 2000): Their human and financial capital improves their utilization of new knowledge encountered in interactions with foreign investors. Moreover, their motivation is high, as the institutional framework is market-oriented and their performance is dependent on their own efforts, with little protection from governments.

Dynamics. As countries advance from low- to middle-income levels, the technological gap declines, thus reducing the potential knowledge gains from demonstration effects. At the same time, local firms are more likely to face head-on competition as market segmentation and protection decline. Yet their capability to react strategically remains weak, because they lack experience with this sort of competition, or with advanced technological knowledge that would allow them to upgrade further.

As countries advance further from middle- to high-income levels, beyond a certain threshold

they develop the capability to stand up to foreign investors and raise their competitive edge by upgrading their own competitiveness (Liu et al., 2000; Perez, 1997). At the same time, their motivation to do so is enhanced by institutional frameworks rewarding performance. Taking the negative effects at lower levels and the positive effects at higher levels together suggests a U-shaped relationship between the level of economic development and spillover effects:

Main proposition: The host country's level of development influences FDI spillovers in a curvilinear way, taking a U-shaped form.

Economic development encompasses many dimensions. While it is closely associated with a country's level of income, it also incorporates human and institutional aspects. We thus explore three key dimensions of economic development to test our main proposition: income, human capital, and institutional development.

Level of income is a direct measure of economic development. Host countries at very low levels of income may benefit from demonstration effects and other indirect benefits, yet the effect declines when foreign and local firms compete directly for markets and resources. Beyond a threshold, however, local firms acquire the capability to react strategically, and thus to translate competitive pressures and technology exposure into increased productivity and competitiveness. Moreover, at high levels, income provides financial resources that enable firms to acquire capabilities to utilize knowledge transfer. Hence our first hypothesis offers a direct test of our main proposition:

Hypothesis 1a: The host country's level of per capita income influences FDI spillovers in a curvilinear way, taking a U-shaped form.

Human capital is a major foundation of firms' capability to react to foreign entry, and to make use of knowledge spillovers. It comprises both general education and specialist competences such as skills and learning processes of R&D (Lorentzen, 2005), and is commonly proved by measures such as educational achievements and R&D expenditures (Barrios et al., 2004; Kathuria, 2001; Kinoshita, 2001).

At low levels of human capital a large technology gap facilitates demonstration effects. With increasing human capital formation these benefits

diminish while direct competition increases, for instance in markets for managerial talent. Beyond a threshold level of human capital local firms develop their own absorptive capacity, which strengthens their capability to take initiatives that enhance productivity. The more human capital advances, the more firms are able to retain qualified staff, absorb latest technologies, and thus enhance their productivity. Hence the relationship between human capital and knowledge spillovers is likely to be curvilinear:

Hypothesis Ib: The host country's level of human capital influences FDI spillovers in a curvilinear way, taking a U-shaped form.

The *institutional development* of the host economy influences both the national innovation system and the patterns of competition between foreign and local firms (Lundvall et al., 2002; Nelson, 1993). Weak institutions tend to be associated with inefficient markets, network-driven business practices, and protected niches for local firms (Khanna & Palepu, 2000; Peng, 2003). Foreign investors may thus be constrained in their organizational forms (Meyer, Estrin, Bhaumik, & Peng, 2009), while local firms may take advantage of such business practices and weak intellectual property protection to attain knowledge that foreign investors may otherwise be able to prevent from diffusion. Such possibilities, however, diminish with the advance of legal institutions.

Improvements of institutions from a low level would remove regulation protecting incumbents and allow foreign investors to fully exploit their competitive advantages at the expense of local firms. Especially in early stages of liberalization, inertia at both national and firm level may inhibit organizational change and strategic flexibility, such that local firms may be ill prepared for direct competition (Konings, 2001). However, beyond a threshold of institutional development, local firms have developed competitive positions in their home markets, and are thus both motivated and capable to face foreign investment competition. They thus are more likely to counter the challenge by raising their own productivity. Hence we propose:

Hypothesis Ic: The host country's level of institutional development influences FDI spillovers in a curvilinear way, taking a U-shaped form.

Hypotheses Ia to Ic suggest a curvilinear relationship for several aspects of development. Support for all three sub-hypotheses would represent very strong support for the main proposition. However, the nature of development is such that human and institutional development are mutually interdependent, and jointly influence per capita income. Thus the logic of economic development leads us to expect that the effects of Hypotheses Ia to Ic cannot be separated.

International Trade

A key aspect of the institutional environment is the foreign trade regime (Bhagwati, 1994; De Mello, 1997; World Bank, 1993). Firms facing competition from imports are likely to develop the strategic flexibility and learning practices that also strengthen their ability to learn from foreign investors (Keller, 1996). They thus are likely to have developed *motivation* and *capability* to react to foreign entry in ways that enhance their productivity and market position. Moreover, with an open trade regime, local firms can acquire complementary investment goods and technologies that help them absorb knowledge from foreign investors (Hoekman et al., 2005).

An open trade regime entails few restrictions on international trade, and thus encourages investors to design location and sourcing strategies based on efficiency considerations. Inward foreign investors are thus likely to be highly integrated in international trade, and to adopt internationally competitive technologies. In consequence, local firms can observe latest technologies and face a tougher competition, which enables them to develop capabilities to act flexibly in a volatile environment.

Moreover, an open trade regime facilitates export-oriented foreign investors, which may enhance local firms' business opportunities directly when integrating into MNE supply networks, and indirectly by providing information on foreign tastes, market structure, competitors, distribution networks and transport infrastructures (Kokko, Tasini, & Zejan, 2001). It may even help local firms to become exporters themselves (Aitken, Hanson, & Harrison, 1997).

Thus openness to international trade may generate a more competitive market environment and a higher level of technology exchange. In support of this argument, empirical studies find a stronger association between FDI and GDP growth in countries with export-oriented rather than

import-substituting policies (Athukarola & Chand, 2000; Balasubramanyam, Salisu, & Sapsford, 1996). Thus we expect that FDI combined with trade openness will be associated with higher productivity increases of local firms:

Hypothesis 2: FDI spillovers are more likely, the more open the host country is to international trade.

DATA AND METHODOLOGY

Our Database

Our database encompasses all known published and unpublished empirical papers that estimate FDI

spillovers by the sensitivity of local firms' productivity to the presence of FDI in industry. They have been collected by searching the EconLit database and the Internet using keywords such as "spillovers from technology transfer" and "productivity FDI spillovers", and through review papers on productivity spillovers. We have identified 66 empirical studies using such research designs in developing countries (23 studies), transition economies (22) or developed countries (21). (Table 1)

Many of the early studies, starting with Caves (1974), find significant positive effects. Also, recent studies in the UK suggest positive effects (Haskel et al., 2007; Liu et al., 2000), whereas results from southern European countries are more mixed

(Barrios et al., 2004; Flores, Fontoura, & Santos, 2007). Early research in developing economies, such as Mexico (Blomstrom, 1986), Uruguay (Kokko et al., 1996) and Indonesia (Sjoholm, 1999), points to significant positive productivity spillovers. In contrast, recent panel data studies show

negative effects, in two major studies by Aitken and Harrison (1999) on Venezuela and Kathuria (2000) on India. For transition economies the evidence is equally unclear. Liu (2002) in China, Yudaeva, Kozlov, Melentieva, and Ponomareva (2003) in Russia, and Sinani and Meyer (2004) in Estonia

find positive effects, whereas other studies find negative effects in Bulgaria, Romania (Konings, 2001) and the Czech Republic (Djankov & Hoekman, 2000). Hence the overall evidence is rather inconclusive.

Early studies use cross-sectional data, yet as panel data techniques have become more available, most recent studies use panel data, in total 43 of 66 studies. Twenty papers use industry-level data, while the remainder use firm-level data. Spillovers are proxied by the presence of foreign investors in the industry, which, however, is measured by their share in industry employment (25), industry equity capital (28), or industry sales, output or value-added (25).² The performance of recipient firms is measured by a proxy of productivity, such as output per employee or value-added per employee (29), value-added (11) or total factor productivity or output (30), where any of these measures may use level, log of level or growth data.

Many studies report multiple regression analyses using alternative definitions of the spillover variable or the dependent variable, or they estimate spillovers for different countries and time periods. From these studies we include all spillover estimates in our meta-analysis.³ With these multiple results from some studies, the database consists of 124 observations. However, two studies with three spillover estimates (Chuang & Lin, 1999; Sjöholm, 1999) report *t*-values that are ten times larger than the mean. Without these outliers from the analysis, the final database includes 121 observations.⁴

Methodology

Our meta-regression analysis regresses *t*-statistics on country variables as well as independent study

characteristics to investigate the patterns of prior results (Stanley & Jarrell, 1989). This approach allows us to investigate moderating effects on a relationship explored in earlier empirical research (Figure 3).

Our sample includes multiple spillover estimates for many studies, which allows us to analyze the data as panel. However, fixed and random effects in a meta-analysis refer to assumptions about heterogeneity of the effect estimates and not to assumptions of the variation across time and firms (Hedges & Vevea, 1998). Under the fixed-effects models the effect size in the population is assumed to be the same across studies (the homogeneity assumption). In the random effects models each study has a different effect size (the heterogeneity assumption).

We test for fixed vs random effects meta-analysis with a heterogeneity test (Lau, Antman, Jimenez-Silva, Kupelnic, Mosteller, & Chalmers, 1992). Based on this test, we can reject the null hypothesis of no heterogeneity at 1% significance level. Hence we employ the random-effects model. The advantage of estimating a random-effects meta-analysis is that it integrates in the model the between-studies heterogeneity not explained by covariates. Maximum likelihood estimates of model coefficients are then obtained, with weights being the between-study variance (Thompson & Sharp, 1999). We thus estimate the following random meta-analysis model:

$$Y_{ij} = \alpha_i + \gamma_c \Gamma_c + \beta_{ij} X_{ij} + \varepsilon_{ij} \quad (1)$$

where Y_{ij} is the *t*-statistic⁵ of the spillover coefficient derived from the *j*th regression in the *i*th study, α_i represents random effects that control for the

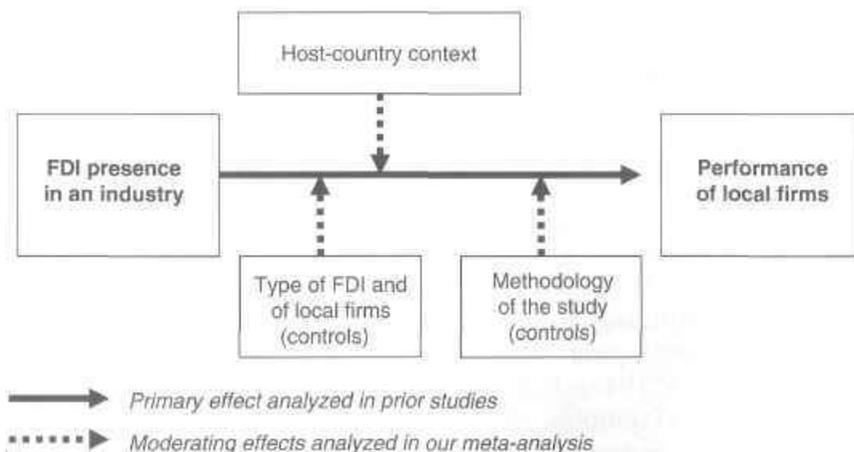

Figure 3 Moderating effects of contextual variables on FDI spillovers.

commonality and dependency of estimates within and across studies, Γ_c is a vector of explanatory variables that account for cross-country variations (including their quadratic terms where appropriate), and X_{ij} is a vector of control variables for study characteristics.

Explanatory Variables

We test our hypotheses by introducing country-level variables in the meta-regression. Hypothesis 1a is tested using *GDP per capita* of the host economy, measured at constant prices of the year 2000, as reported in the World Bank's World Development Indicators. Hypothesis 1b is tested using several indicators of human capital. *Tertiary education* is measured as the gross enrollment ratio in tertiary education;⁶ *R&D expenditures* refer to R&D expenditure of the private sector as a percentage of GDP; *patenting* is measured by patents granted to host country residents, scaled in patents per billion dollars, weighting them with GDP (at 2000 constant prices). The sources for these data are respectively the World Bank's Education Statistics, the World Bank's World Development Indicators, and the World Intellectual Property Office's statistics.

Hypothesis 1c is tested using two institutional development variables. *Economic freedom* is measured by a subset of five items of the Economic Freedom Index from the Heritage Foundation. We selected the five items that most closely relate to the notion of institutions guaranteeing the efficiency of markets: business freedom, trade freedom, property rights, investment freedom, and financial freedom. *Transparency* is measured with the corruption perception index provided by Transparency International: high values of this index indicate low levels of corruption. Hypothesis 2 is tested using *trade openness* of the host economy, which is measured by the sum of exports and imports divided by GDP, which we also obtained from the World Bank's World Development Indicators.

A methodological issue in constructing these data concerns the relevant time, because the underlying studies used data from different time periods. We thus constructed all these variables as the average over the data period of the underlying studies. For instance, if a study investigates FDI spillovers for the period 1995-2000, we construct averages of respective variables for this period. Where data are missing for the required time period, we use data for the nearest year available. This,

however, has been an issue only with the Economic Freedom Index.

Control Variables

The underlying studies vary in their methodologies and measurements (Gorg & Strobl, 2001): we thus need to control for these issues. First, we include the log of the number of observations, to control for sample size of a study. This is a major concern, as the number of observations per study ranges from 20 in Blomstrom and Wolff (1994) to 32,521 in Aitken and Harrison (1999).

Second, we include a dummy for panel vs cross-section studies. Cross-section studies do not permit us to control for possible reverse causality, as foreign investors may seek more productive industries, which may bias estimates upward (Aitken & Harrison, 1999). Third, studies vary in their level of analysis, as some use firm-level data, whereas some cross-sectional studies use industry-level data. Fourth, spillovers vary with the nature of the foreign investment in the industry. In particular, foreign presence has been measured by the share in, respectively, industry sales, employment or capital. We introduce two dummies for studies using respectively the share in employment or equity capital.

Fifth, the studies by Schoors and van der Tol (2002), Yudaeva et al. (2003), Javorcik (2004), Liu (2008) and Halpern and Murakozy (2007) analyze both horizontal and vertical spillovers in the same regression. However, the horizontal effect may be affected by the simultaneous inclusion of vertical effects. Therefore we introduce a dummy to control for studies that include vertical spillovers. Finally, some studies control for the effect of technology gap, which may cause variations of effects across firms within the industry (Thuy, 2005; Tian, 2007). Therefore we include a dummy to control for these studies. This and the previous control variable are in addition to the set of independent variables used by Gorg and Strobl (2001). Finally, our time trend variable refers to the median year of the data period covered, with 1970 taking the value of zero and 1995 taking the value of 25.

Table 2 presents means, standard deviations and the correlation matrix for all variables. *GDP per capita*, *transparency*, *economic freedom*, *tertiary education* and *R&D expenditures* are strongly correlated with each other. Hence including them together in regressions may lead to biased coefficient estimates. We have thus assessed possible multicollinearity on the basis of variance inflation factor tests. These

***, **, significant at 1% and 5%, respectively.

Notes: GDP per capita is scaled per US\$1000; patents granted to residents is scaled per US\$billion; Corruption Perception Index varies from 0 (highly corrupt) to 10 (highly clean); Economic Freedom Index varies from 0 (repressed) to 100 (free); gross enrollment ratio in tertiary education is the total enrollment in tertiary education, regardless of age, expressed as a percentage of the population in the official age group corresponding to this level of education; R&D expenditures is the expenditure of the private sector as a percentage of GDP.

show that dropping *GDP per capita*, *transparency* and *economic freedom* removes the multicollinearity.

We have used this information to design our estimation strategy. In Table 3, we estimate jointly and separately the three explanatory variables that are not highly correlated. In Table 4, we estimate the hypothesized nonlinear effects controlling for *trade openness* and *patenting*.

RESULTS

Table 3 presents the regression results for the linear and nonlinear effect of *GDP per capita*, *trade openness* and *patenting*. The curvilinear effect of per capita income is tested in Model 2, where both *GDP per capita* and its square are significant at the 1% level. This result is robust to the addition of additional variables in Models 3-5. This nonlinear relationship between a country's level of economic development and its received FDI spillovers supports Hypothesis 1a. Hence rising incomes in low-income economies reduce FDI spillovers; only above a certain threshold does this relationship turn positive.

Figure 4 illustrates this effect of an increase of *GDP per capita* on spillovers by depicting the t-statistics that our regression results predict for the underlying studies. The U-shaped curve shows that low-income countries such as India and China benefit on average from FDI spillovers, but this effect declines as they advance to the levels of, for instance, Russia, Hungary or Mexico. On the other hand, among high-income countries such as the UK and USA the curve has an upward slope. Thus both very poor and very rich countries appear to benefit more from FDI spillovers than do countries in the intermediate range.

Model 5, 8 and 9 (Tables 3 and 4) test for the curvilinear effect of the human capital variables, namely *patenting*, *tertiary education* and *R&D expenditures*. In support of Hypothesis 1b, these results show that the quadratic forms of *patenting*, *tertiary education* and *R&D expenditures* are significant at the 1% level. These results point to the curvilinear relationship between human capital and spillovers - independent of how it is measured. In all cases the linear term is negative, whereas the quadratic term is positive. Hence spillovers are least likely at intermediate levels of human capital.

The threshold level beyond which the significance of spillovers increases is in all cases in the relevant range of the variable.⁷ The lowest effect of *patenting* occurs at 2.93 granted patents per billion US\$. In our dataset, 58.63% of observations are

Notes: (1) Absolute value of *z*-statistics in parentheses; (2) *significant at 10%; **significant at 5%; ***significant at 1%; (3) τ^2 is the unexplained between-studies variation: its lower bound is zero, in which case the included covariates explain all of the heterogeneity between studies. Hence the smaller and closer to zero this value, the better the model.

below this critical value. The threshold for tertiary education is 32.75%, with 59.5% of observations being below this level. For *R&D expenditures* the threshold is 1.33%, and 78.5% of our observations are below this critical value. In each case, countries below the critical value include developing economies, transition economies, and southern European countries such as Greece, Spain and Italy.

Models 6 and 7 (Table 4) test the curvilinear effect of institutional variables, namely *transparency* and *economic freedom*. In both cases the linear terms are negative and the quadratic terms are positive, both significant at the 1% or 5% level. Hence we find

support for Hypothesis 1c. The curvilinear effect of economic freedom suggests that countries with a moderate degree of institutional development may least benefit from spillovers. The threshold level for *economic freedom* is 52.16, with 28.1% of the observations below this level. Hence most of the countries in our sample enjoy economic freedom above the critical level, and can thus expect increases of FDI spillovers when they further enhance their institutional development.

The threshold level for *transparency* is 5.69, and 67.77% of the observations in the dataset are below this level. This result suggests that spillovers are

higher for high levels of corruption than at intermediate levels. At high levels of corruption, local firms may be able to shield themselves from foreign competition, and thus avert direct confrontation and being crowded out. Moreover, firms in corrupt countries may be able to use illegitimate means to attain technologies from foreign investors.

Models 3 and 4 (Table 4) test for the linear and nonlinear effects of *trade openness*. The linear effect in Model 3 is significant, which supports Hypothesis 2, whereas the nonlinear specification (Model 4) is not significant. This finding is consistent with the argument that, on average, an open trade regime enables and motivates local firms to increase their productivity (De Mello,

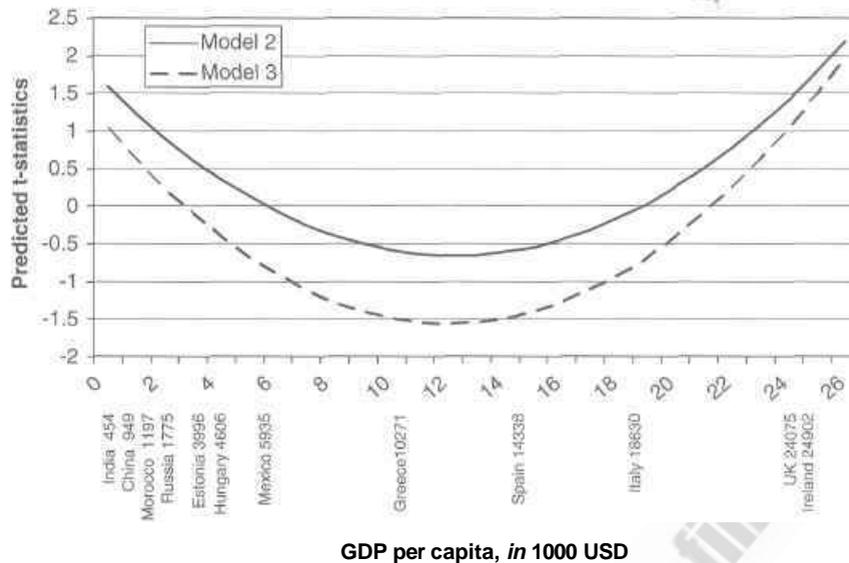

Figure 4 The effect of per capita income on the significance of FDI spillovers.

Note: This figure has been constructed by inserting GDP per capita values in Models 2 and 3 in Table 3, while keeping the other variables at their median value. All GDP per capita values have been deflated to the year 2000.

1997; Kokko et al., 2001). This positive relationship appears to apply to all countries, contrary to the other country-level effects analyzed in this study.

With respect to control variables, our results show that studies using cross-sectional data, on average, find stronger spillover effects. This finding is in line with Gorg and Strobl (2001). However, in addition, we also find that studies that use industry-level data find stronger spillover effects, and that studies controlling for vertical spillovers when estimating horizontal spillovers tend to find less significant positive spillover effects. This is a very interesting finding, in that studies that do not account for vertical spillovers seem to overstate the likelihood of horizontal spillovers.

In addition to the regressions reported in Tables 3 and 4, we have tested a number of other specifications that substantively yielded the same results. For instance, a measure of secondary education yielded results very similar to those for tertiary education. We moreover run the same regressions on a subset of panel data studies only. The results are substantially identical, except that the coefficient for trade openness is not significant (possibly because of the smaller sample size). Thus, despite the 5% significance in our main analysis, we cautiously interpret this result as only weak support for Hypothesis 2.

DISCUSSION AND CONCLUSION

Theoretical Contribution

We have applied and advanced the awareness-motivation-capability framework of recent management research (Chen, 1996) to analyze a research question at the interface between economics and management studies, namely the reaction of local firms to inward foreign investors. This application suggests further potential for applying it to firm- or industry-level studies of spillovers, where more concise measures may be available. The modification required is to incorporate the potential benefits that may be gained, which relate to the size of the technology gap.

Our results support the view that FDI spillovers are influenced by the specific context of the study. In particular, we proposed that FDI spillovers have a curvilinear relation with the level of economic development, and we have assessed this proposition with respect to three dimensions of development: income, human capital and institutions (Hypotheses 1a to 1c). Hence very poor and very rich countries appear to benefit most from inward FDI. The consistency of the nonlinear relationship across a range of development indicators provides very strong evidence in favor of our main proposition.

While these results confirm our main theoretical argument, they also raise important issues for

future theory development. In particular, how do human capital and institutional development interact in building the motivation and capability of local firms: are they separate effects, or is one of them mediating the effect, of the others? For instance, per capita income may be mediated by human capital and institutional frameworks, rather than affecting firms' productivity increases directly. Moreover, which institutions affect the motivations of local firms, and how? Applications of dynamic competition theory along these lines may further enhance the emerging institutional view of international business strategy (Meyer et al., 2009; Peng et al., 2008).

Policy Issues

Our study suggests that both low- and high-income economies are likely to benefit from FDI spillovers, yet our theoretical discussion suggests that the underlying forces creating the spillovers may be quite different. In poor countries demonstration effects may create spillovers with little direct interfaces, whereas in advanced economies spillovers result from complex competitive interactions, and from local firms' strategic reaction to the entry of foreign investors in their industry. This analysis emphasizes that policy instruments to facilitate such spillovers may need to be quite different.

Moreover, policy *vis-à-vis* foreign investors has to consider two effects of institutional change. Institutional development attracts more FDI, as has been shown in a number of studies using indices similar to ours, namely economic freedom (Bengoa & Sanchez-Robles, 2003; Kahai, 2004) and corruption (Cuervo-Cazurra, 2006; Smarzynska & Wei, 2000; Voyer & Beamish, 2004). This effect has to be combined with our result of a curvilinear relationship between FDI and spillovers to extract policy advice.

In advanced economies these effects are cumulative: an improvement of institutions will attract more FDI, and raise the spillovers gained from any one foreign investment project. In less advanced economies the relation is more complex, and our results suggest that policy advice may not be directly transferable. A small improvement in economic freedom, or a reduction in corruption, may reduce the spillover benefits or even turn them negative, while at the same time increasing the volume of FDI. Such countries thus have to be more cautious in designing liberalization programs: in particular, they need to avoid situations where

foreign investors directly or indirectly reap the benefits of residual protectionism.

Moreover, policymakers and development scholars may be concerned whether globalization enhances or depresses spillovers. The positive effect of *trade openness* provides some support for the advocates of trade liberalization, yet it also raises the question of why trade openness has a different effect from other measures of institutional development.

Limitations and Future Research

Many of the limitations of our study arise from limitations of the underlying body of empirical literature. In the meta-analysis we can address limitations of context specificity and small-sample biases. However, other limitations in the literature, such as issues relating to the measurement of spillovers and the need to capture firm-specific effects, remain.

Further research may "bring the firm back" into spillover research, and investigate the characteristics of both foreign investors and local recipient firms (Driffield & Love, 2007; Meyer, 2004, 2008; Spencer, 2008). For instance, some domestic companies may benefit from direct links to foreign subsidiaries via different non-equity agreements, whereas others do not have such links. Our results for control variables suggest that capital-intensive foreign investors may be more likely to generate spillovers, though the effect is not significant.

Moreover, researchers may move from analyzing horizontal spillovers to analyzing vertical spillovers. Most studies in our database are designed to capture horizontal spillovers; they capture vertical spillovers only for suppliers classified in the same industry. However, most supplier relations transcend industry boundaries. Recent research using industry-level input-output data thus offers promising new perspectives (Javorcik, 2004; Merlevede & Schoors, 2008; Schoors & van der Tol, 2002). As yet there are, however, too few studies to conduct a meta-analysis of these types of spillover.

Beyond the literature on the impact of FDI, we hope that our meta-analysis methodology will be used to analyze other pertinent research questions in international business. The variation of business behavior across contexts is a central theme of international business studies, and it is an essential to establish the boundary conditions of theories in use in the field of management (Whetten, 2002). Yet progress is inhibited by the lack of multi-country firm-level datasets, an obstacle that

can be overcome by using meta-regression analysis, as applied here.

In conclusion, we demonstrate that FDI does generate positive spillovers *under certain circumstances*. These circumstances vary with the context of the FDI. We have argued that the prime driving forces of such contextual variation are local firms' motivation and capability to react to foreign entry, which are grounded in their human capital and the institutional framework.

ACKNOWLEDGEMENTS

We are grateful for helpful comments from editor Arjen van Witteloostuijn and two anonymous reviewers for *JIBS*, from seminar participants at the Copenhagen Business School, University of Reading and National Cheng-chi University in Taipei, as well as at the AIB conference in Beijing and the Senjaya-Lall conference at Oxford University. We thank Marcin Winiarczyk for his excellent research assistance in preparing the dataset for us. The Danish Social Science Foundation provided financial support (grant no. 24-01-0152), which is gratefully appreciated.

NOTES

Studies based on firm-level data from multiple east European countries find varying results across

countries. Konings (2001) suggest that the negative effects for Bulgaria and Romania are attributable to the fact that in the early stage of transition the competition effect dominates. Other authors do not provide theoretical reasoning as to why spillovers would vary across countries (Barrios et al., 2004; Damijan, Knell, Majcen, & Rojec, 2003).

²Some studies, such as Kathuria (2000, 2001), Buckley et al. (2002), and Sinani and Meyer (2004), use multiple definitions of the spillover variable. Therefore the sum of the papers by definitions of the spillover variable is larger than 66.

³In papers with multiple similar regressions we take the estimate of the regression with the highest R^2 .

Including the outliers in the analysis results in more significant spillover and firm-level dummy estimates. Therefore we opt for dropping them from the empirical analysis.

⁵For studies that report absolute values of t -statistics, we obtain the correct sign from the reported coefficient of the spillover variable.

⁶Tertiary education is the total enrollment in tertiary education, regardless of age, expressed as a percentage of the population in the official age group corresponding to this level of education.

⁷The critical value is $\partial Y/\partial \Gamma_c = \hat{\alpha}_3 + 2(\hat{\alpha}_4 \Gamma_c) = 0$, where $\hat{\alpha}_3$ and $\hat{\alpha}_4$ are the respective regression coefficients in Model 5, Table 3, and Models 6–9 in Table 4.

ABOUT THE AUTHORS

Klaus E Meyer received his PhD from London Business School. He is a Professor of Strategy and International Business at the School of Management, University of Bath, and an Adjunct Professor at Copenhagen Business School. His research focuses on the strategies, especially entry strategies, of multinational enterprises in emerging economies, especially Eastern Europe and East Asia. His personal website is www.klausmeyer.co.uk.

Evis Sinani received her PhD in Business Economics from Copenhagen Business School in 2004. She is an Assistant Professor at the Department of International Economics and Management at Copenhagen Business School. Her research interests include the impact of FDI on the performance of domestic firms and industry dynamics, as well as on strategies for foreign market entry, exit and survival.
